

Are you a candidate for NMD?

There are always options for you to choose from when deciding on dental treatment. After initial evaluation, your dentist or

treatment counselor will discuss these options with you.

If you are considering major dental procedures such as reconstruction (including cosmetic dentistry), orthodontics, dentures, or if you suffer from head/neck pain or other "TMJ" like symptoms, establishing a precise occlusion becomes very important.

This is when choosing neuromuscular diagnostic techniques can have a positive and long-term impact on the outcome of treatment.

Neuromuscular studies give us added insight into what is going on behind just the appearance of your smile, addressing issues that affect your overall health and well being.

Is NMD for you? We can answer your questions and provide you with additional literature that

can give you more in-depth knowledge of Neuromuscular Dentistry and your treatment options.

Neuromuscular Dentistry May Be The Answer For Headaches And Jaw Pain

If your teeth don't come together just right due to temporomandibular joint disorder (TMJ, or TMJD, meaning the jaw joints), they can become worn down, causing chewing problems as well as a variety of head and neck pain. Many people with these problems clench their teeth together at night, which can damage teeth and dental work. We are trained extensively in neuromuscular dentistry, which addresses these issues. If you have pain in your temples or jaw muscles, or perhaps suffer from earaches, headaches, or problems with your jaw locking up or making popping sounds, you may benefit from neuromuscular dentistry.

Neuromuscular Dentistry (NMD) Beyond The Appearance Of A Smile

The way that your upper and lower teeth come together (your bite or occlusion) is part of a system of teeth, muscles and joints. If your teeth do not fit together properly (misaligned bite), the muscles and joints accommodate - which means they have to work harder to get them together.

A misaligned bite often leads to muscles that are overworked when they should be relaxed, leading to various painful conditions.

**MUSCLES + JOINTS + TEETH =
NEUROMUSCULAR DENTISTRY**

Neuromuscular dentistry considers the entire system that controls the positioning and function of your jaw.

The neuromuscular dentist seeks to establish a jaw position based on a harmonious relationship of the three main factors affecting occlusion - the teeth, muscles and jaw joints. The resulting jaw position is called the neuromuscular bite.

How Is Treatment Performed?

Your dentist may consider various types of dental treatment to improve your smile, to correct a misaligned bite or to relieve a painful condition. To provide you with an optimal bite that gives you a beautiful smile as well as healthy muscles and joints, we will evaluate and study the complex relationship between your teeth, jaw joints and muscles. We then apply neuromuscular principles to build your bite.

NMD begins by relaxing the muscles around the jaw with the use of a TENS device (Myomonitor). The Myomonitor is a battery operated electrical muscle stimulator that delivers a mild electrical stimulus to the muscles of the facial/jaw area, and possibly the neck and shoulder areas, to "exercise" these muscles and cause them to relax.

Sonography is another option available to the NM dentist that allows the dentist to assess the status of the articular disk and jaw joint function.

This information is then used in the doctor's diagnosis to assist in determining the precise point at which your jaw should be in relation to your upper teeth. Rather than relying on your present jaw position as being the best for you, the NM dentist uses this additional objective information to determine if your bite should be left as is or be adjusted to a more optimal occlusion.

Once the dentist has determined where your new bite should be, you will be given a plastic appliance called an "orthotic" to keep your bite in its new position. You may wear this orthotic as an interim step to a more permanent treatment.
